Presented at the 39th Annual Meeting of the APS Division of Plasma Physics

November 19th, 1997

High ℓ_i operation combined with a radiative mantle and recycling control

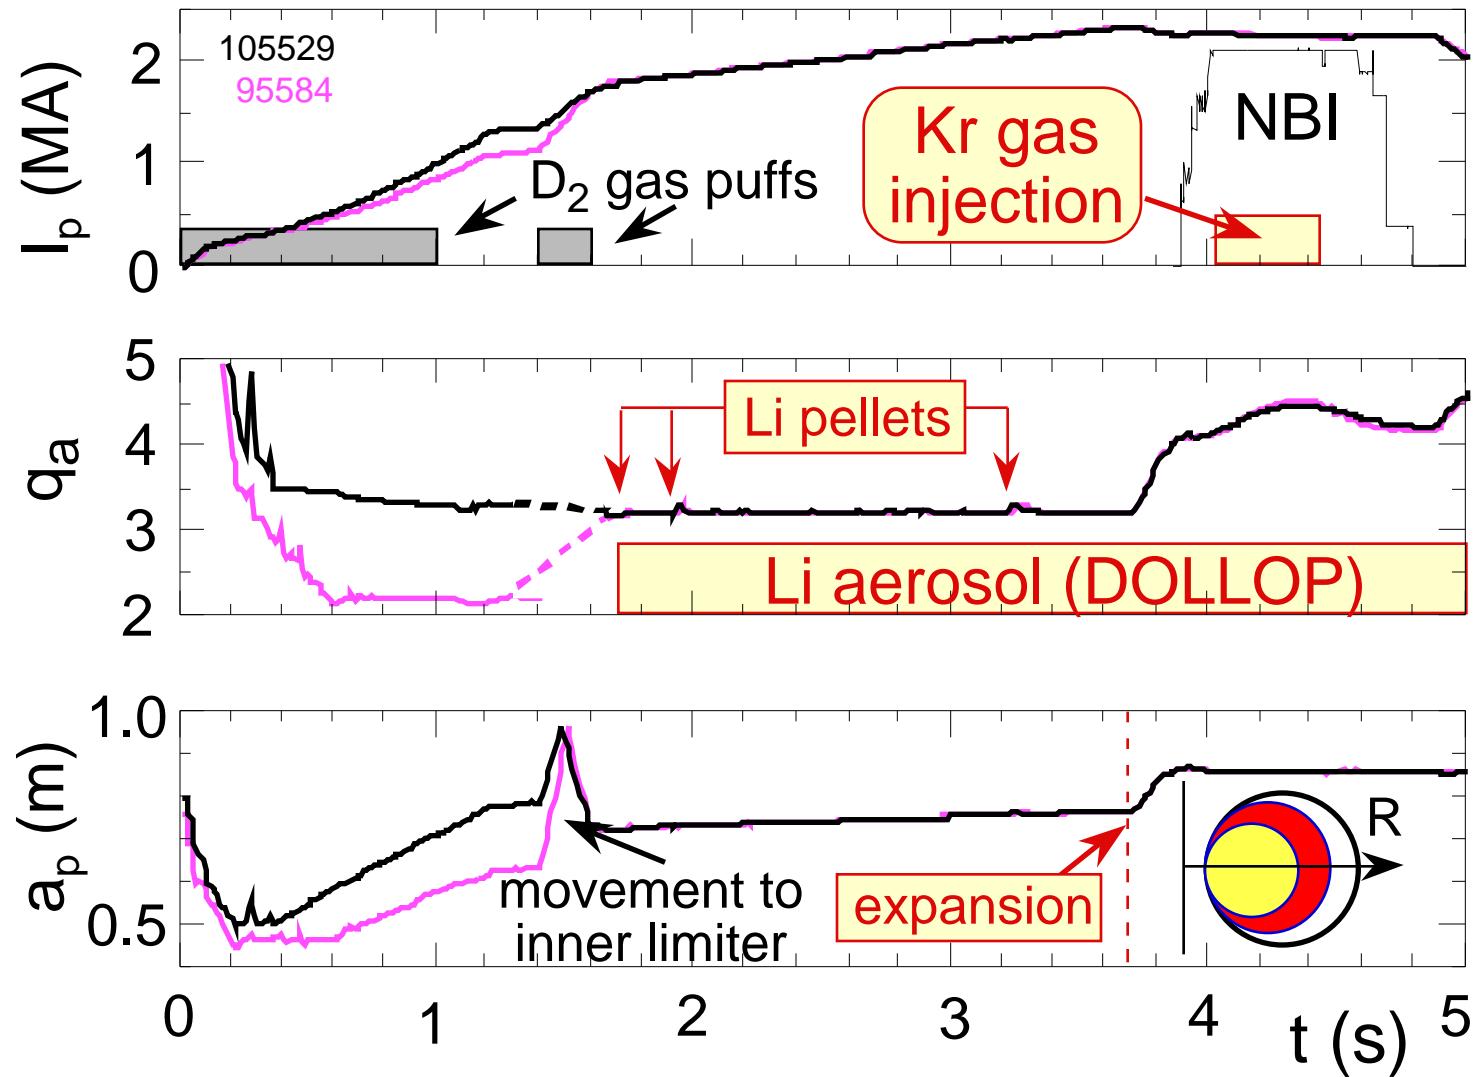

■ Motivation

- Alleviate limiter power handling constraint:
 - stability limit improves as ℓ_i is increased
 - rapid edge density influx (bloom) limits performance, **not stability**

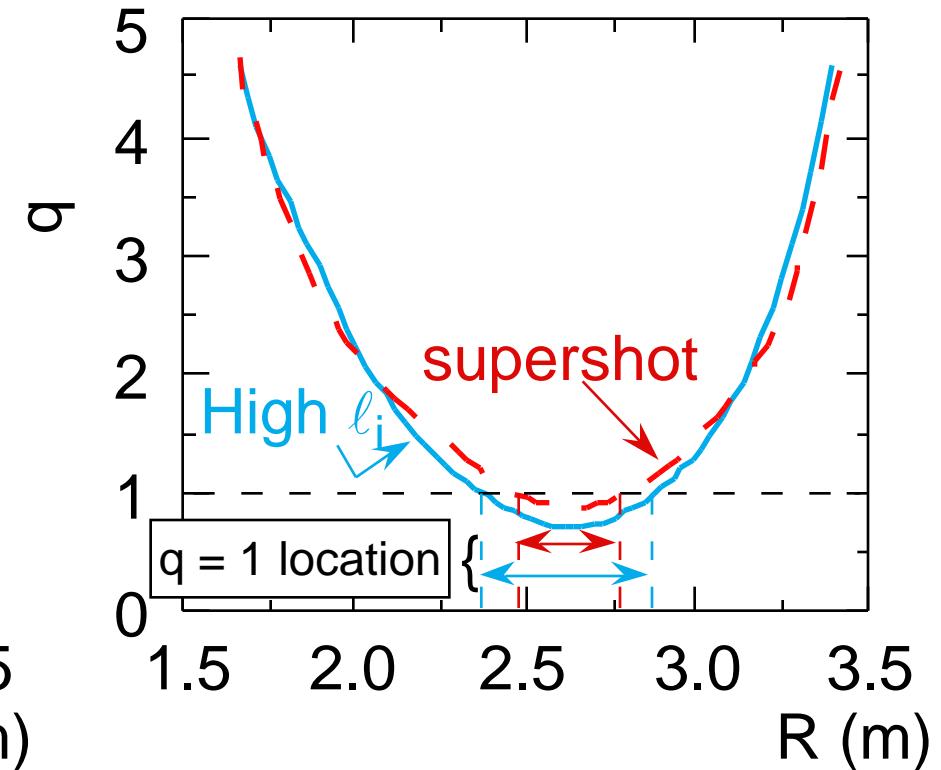

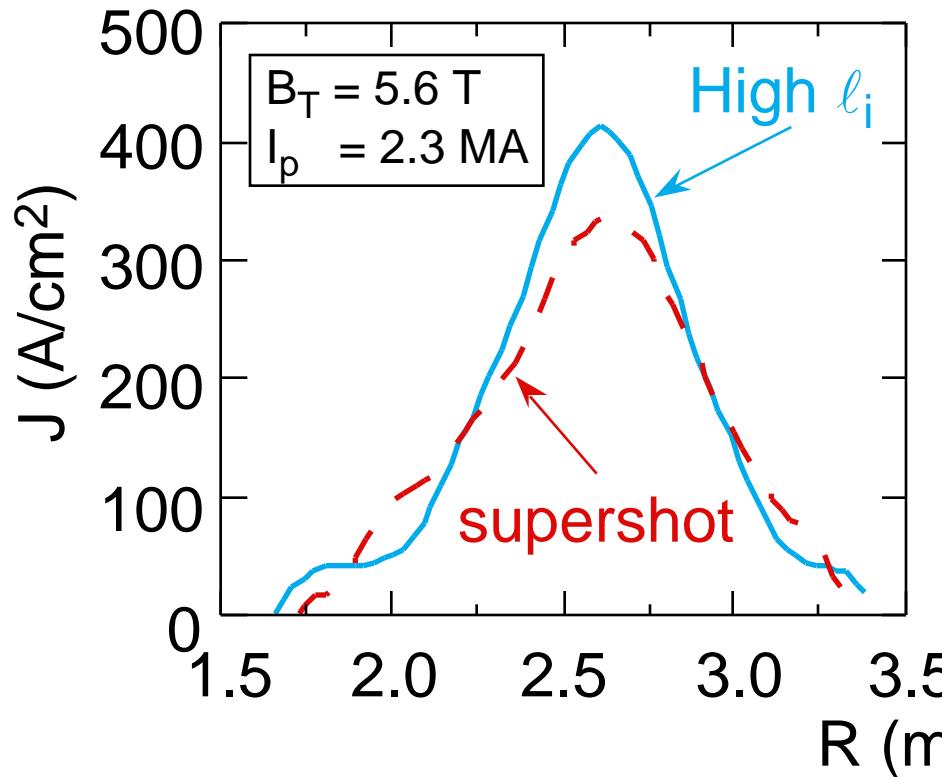

■ Final Experiments

- Incorporate Kr radiative mantle to eliminate blooms
- Increase τ_E by utilizing recycling control with Li conditioning
- Operate high ℓ_i plasma at high $I_p = 2.3$ MA and $B_T = 5.6$ T

Kr Radiative Mantle added to High ℓ_i startup

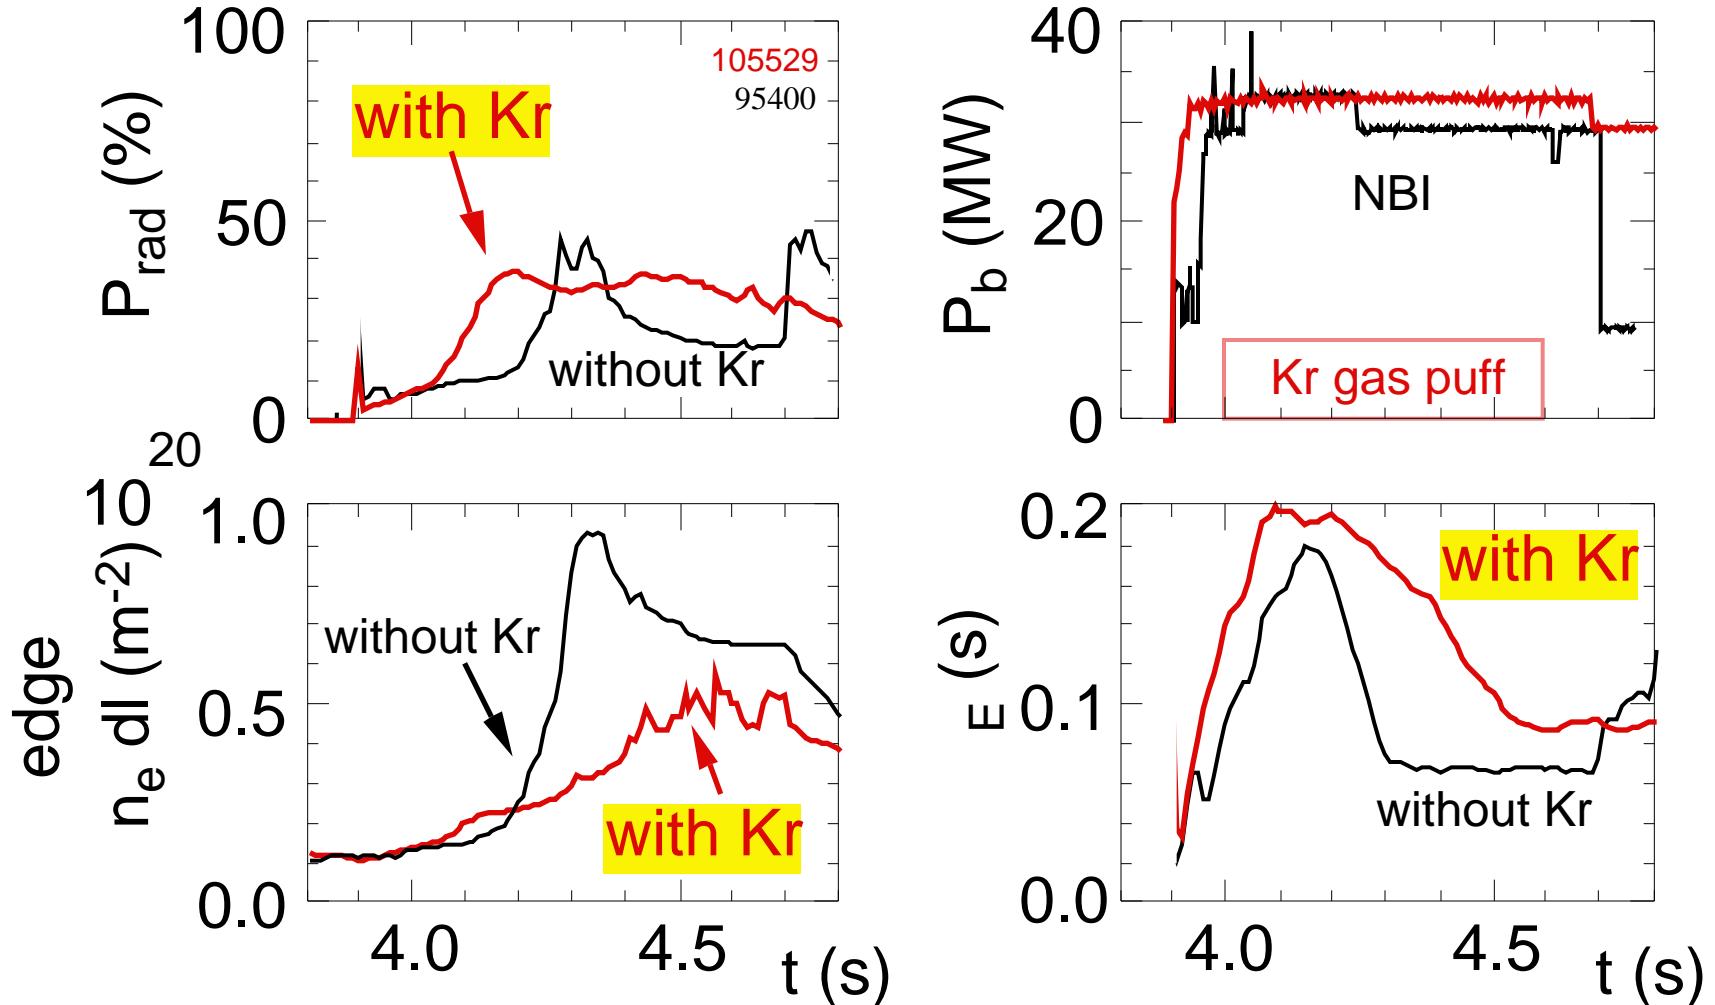

Increased core current results from low q_a startup

- VMEC equilibrium using 21 channel MSE diagnostic
- Increased sawtooth inversion radius verified by ECE T_e measurements

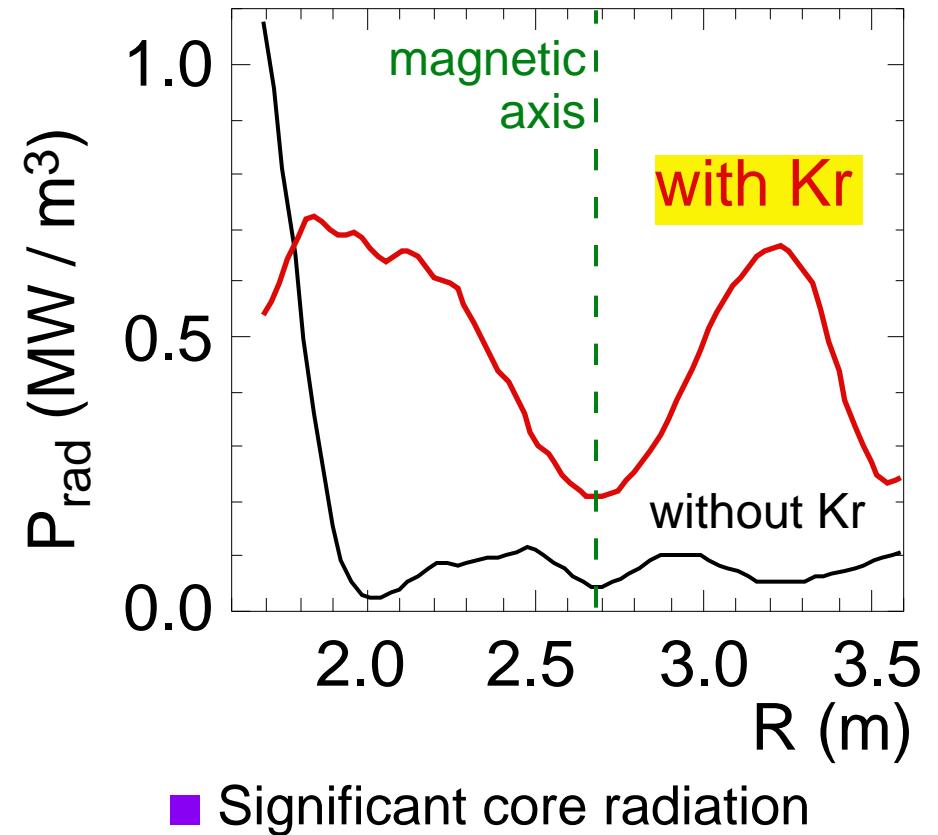

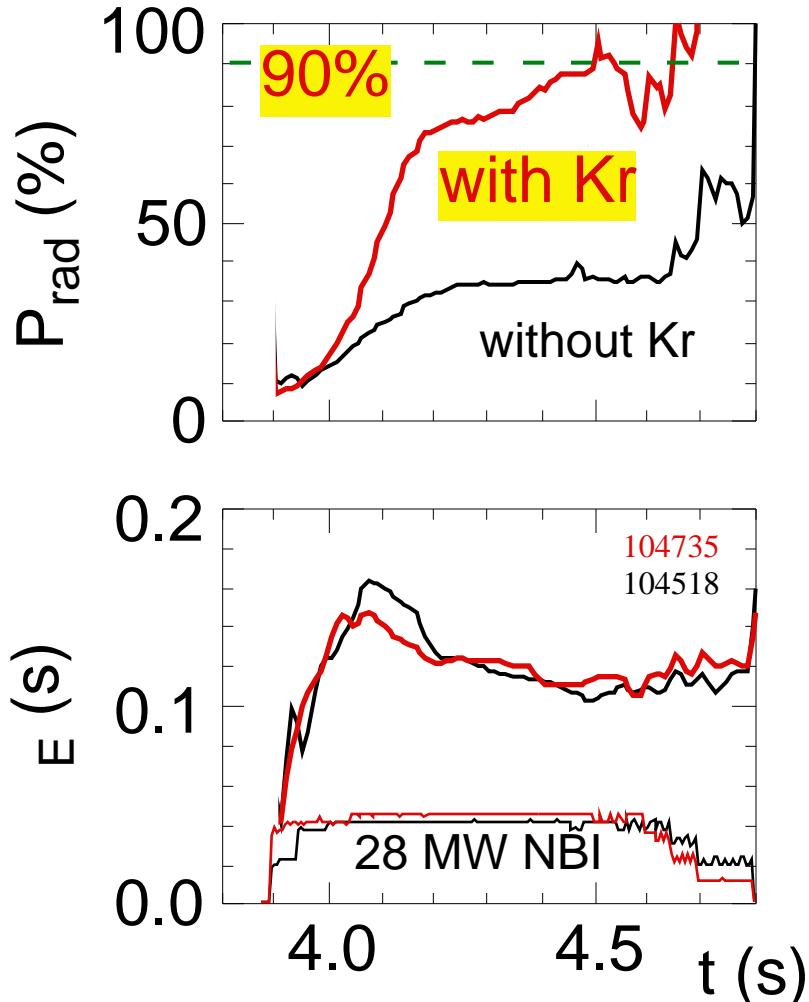

S. H. Batha
FP&T

Higher E_{E} , maintained for longer interval with Kr

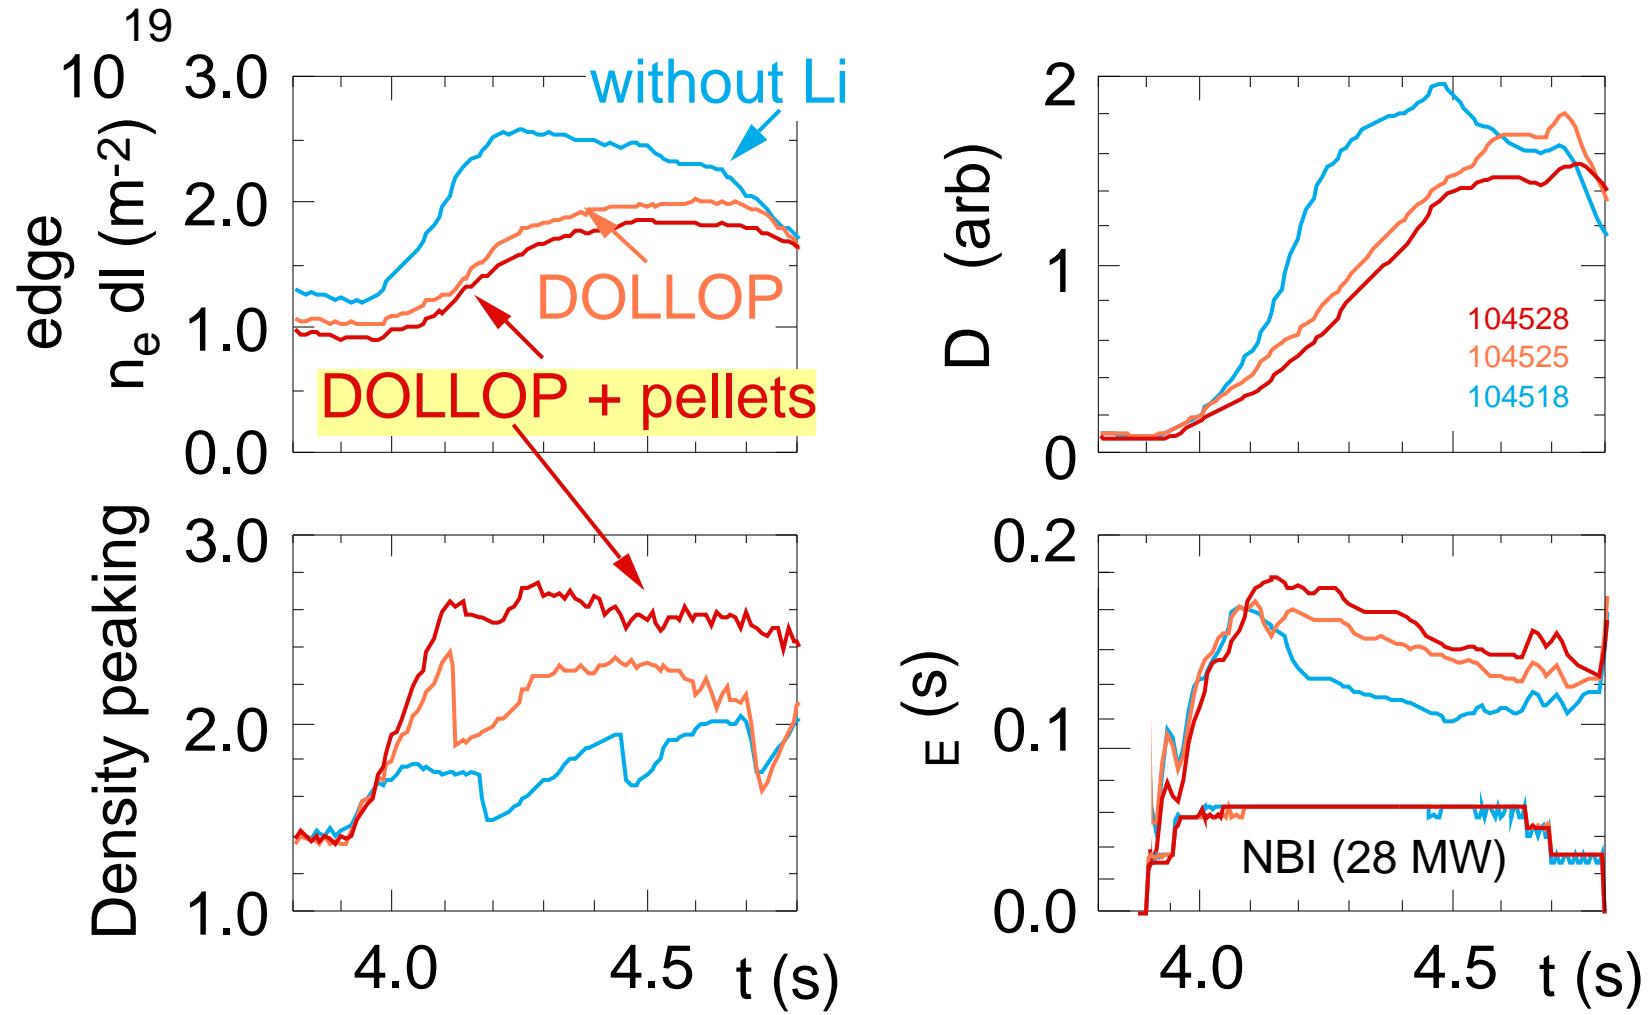

■ Rapid edge density influx suppressed by Kr mantle

Radiated power 90% with no reduction in E

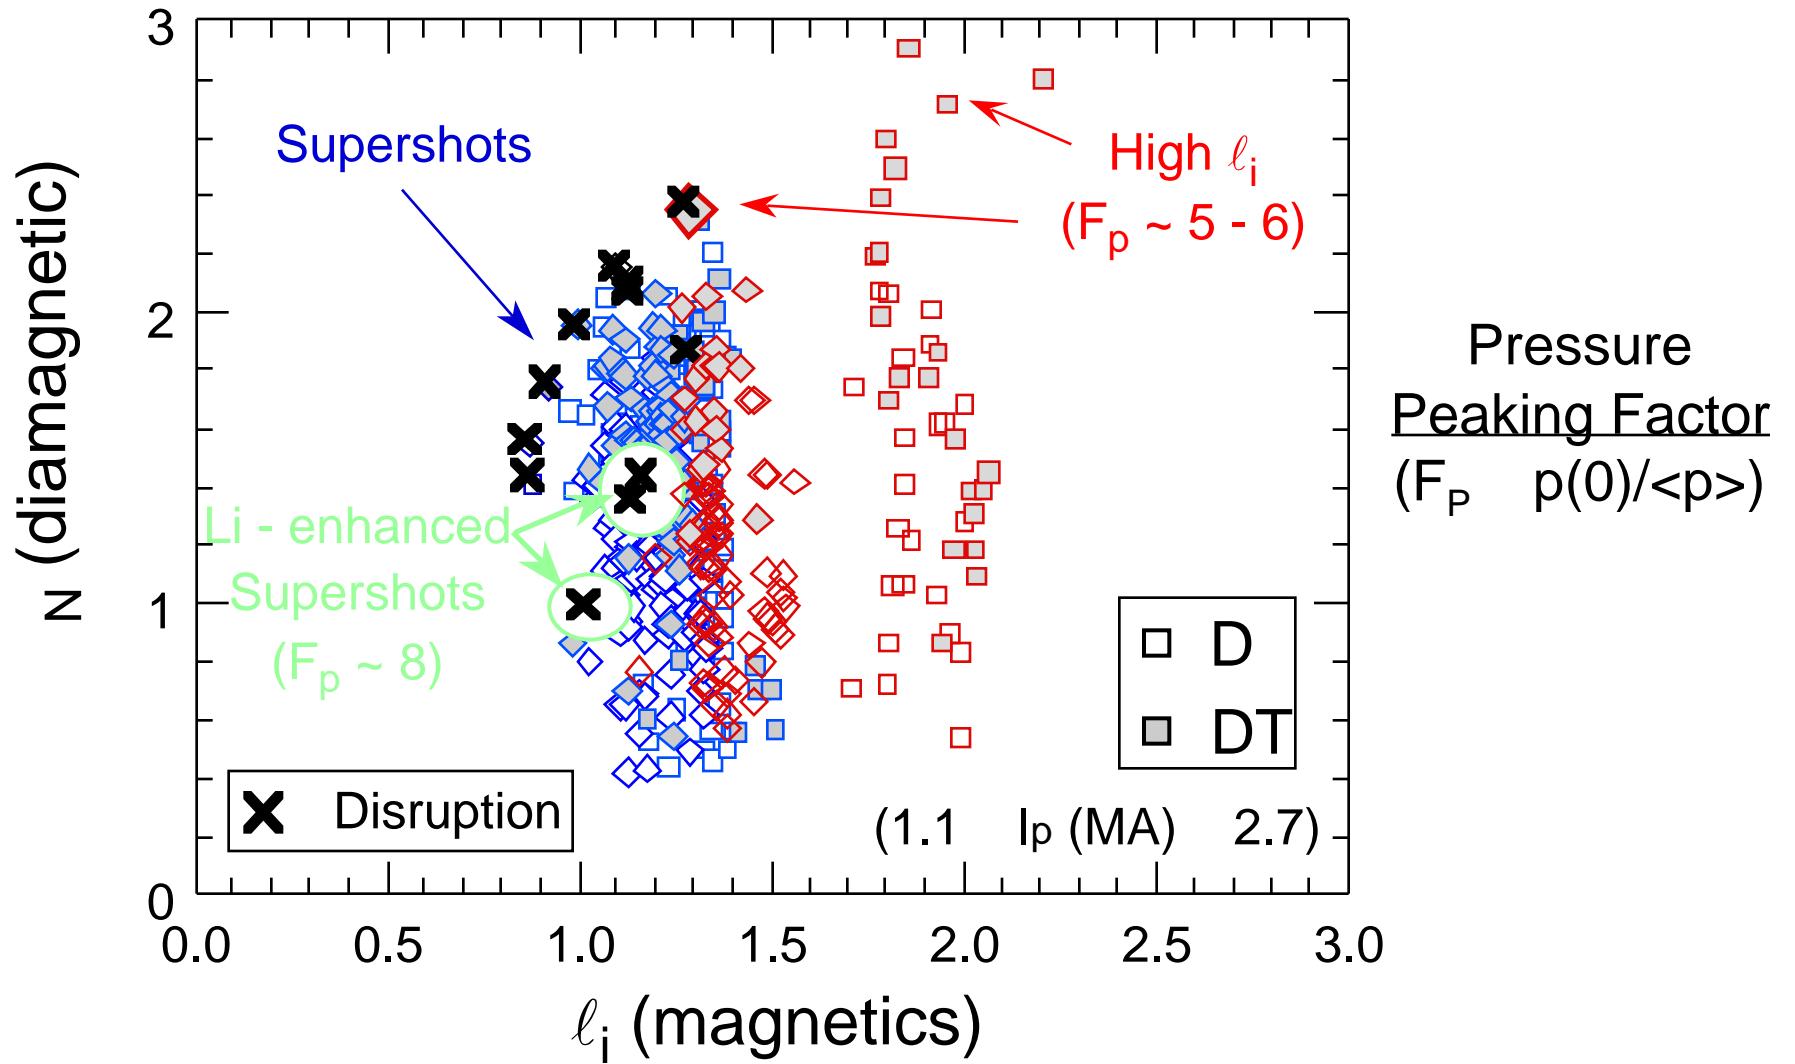

■ Feedback control required to prevent thermal collapse (Hill, oThal1.05)

Recycling control (with Lithium) increases E_{E}

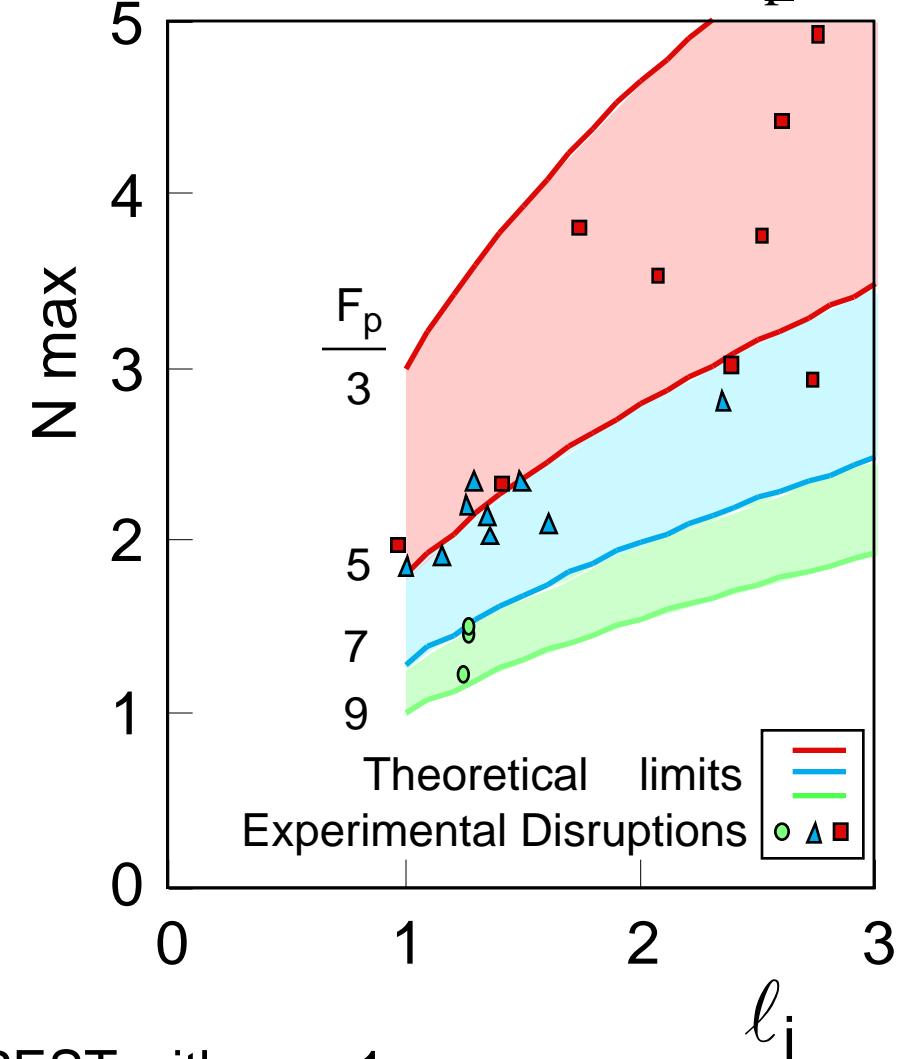

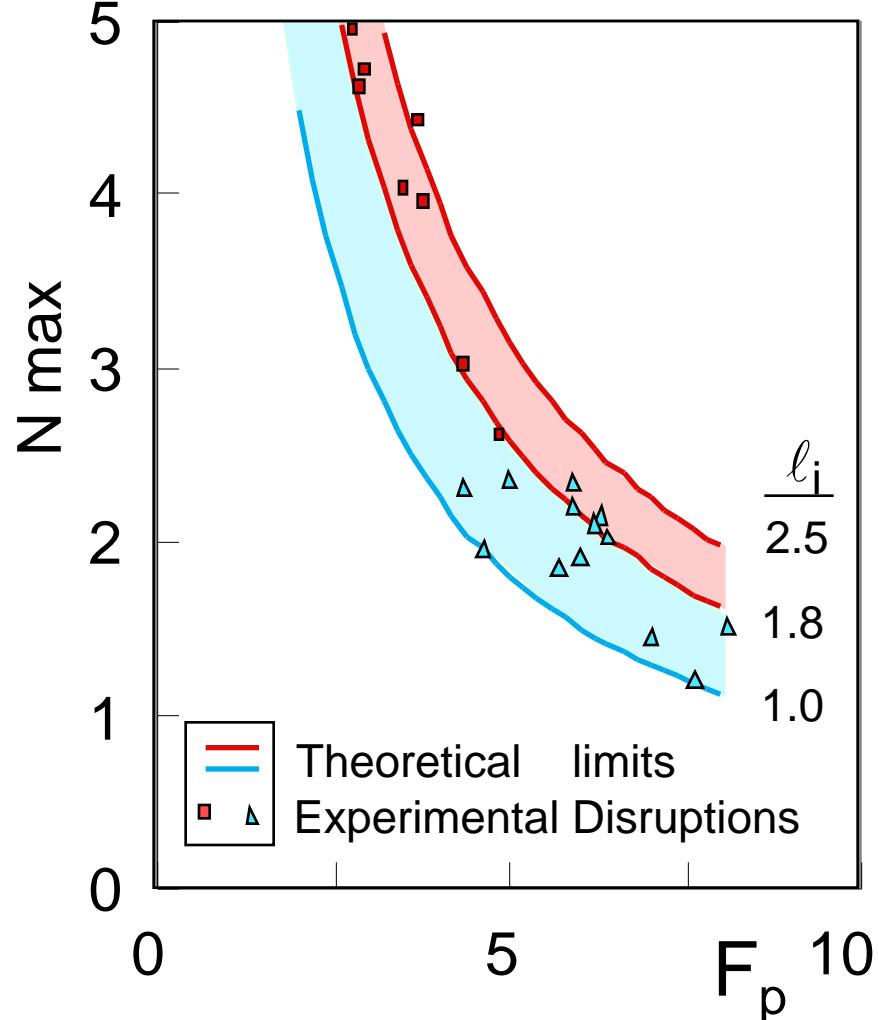

■ Sawteeth stabilized; E_{E} increased by 30%

Achieved N generally increases with ℓ_i

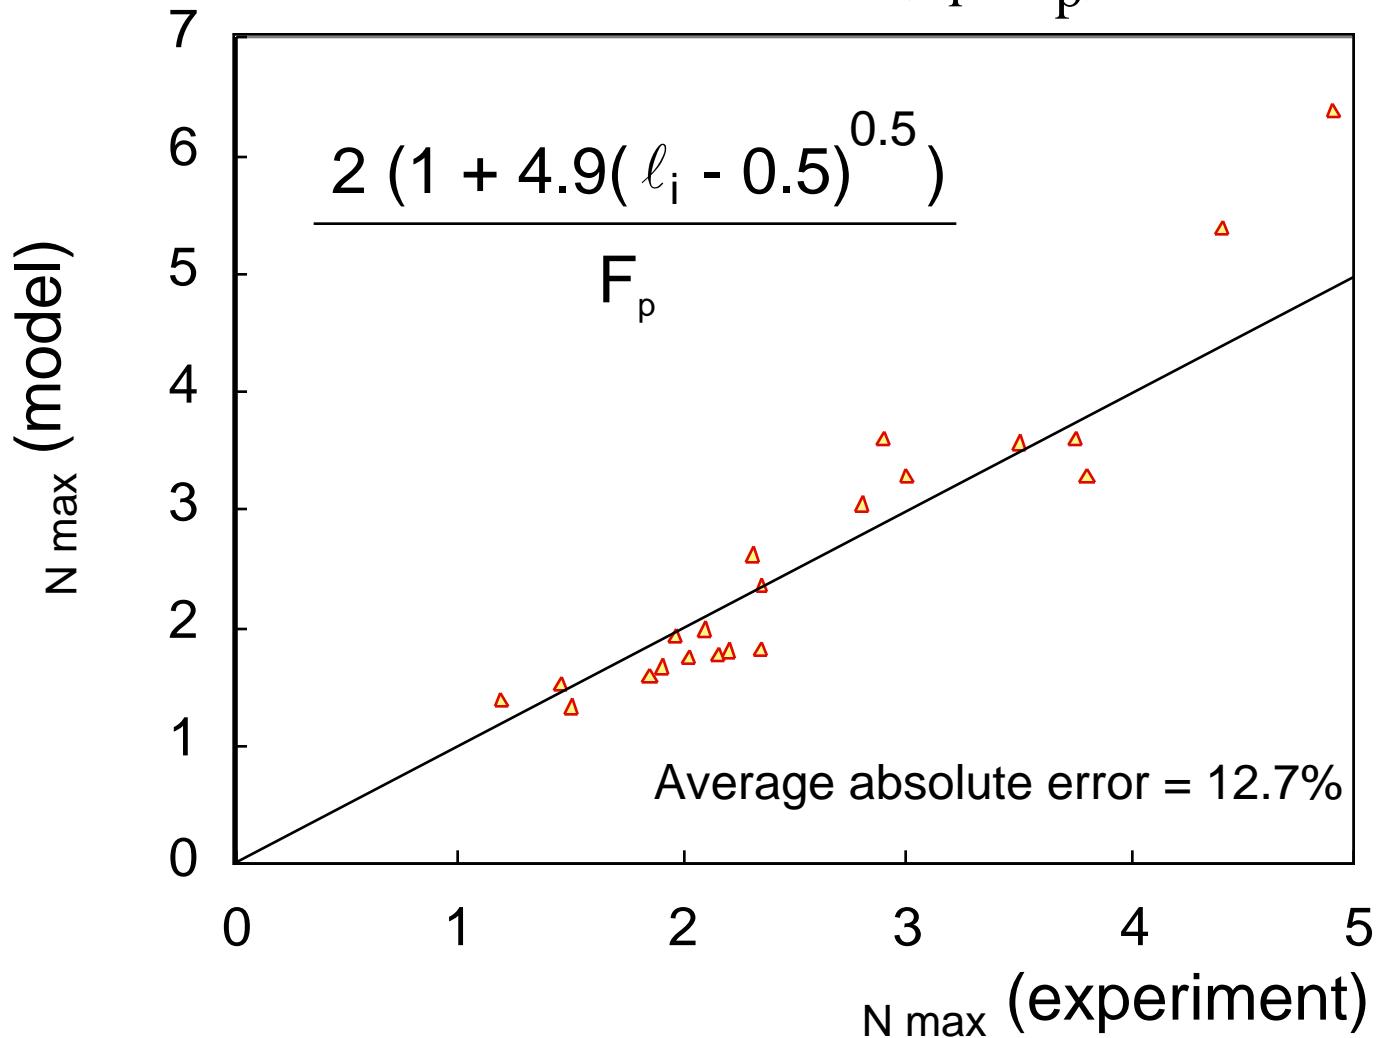

MHD limit increases with ℓ_i , decreases with F_p

Theoretical limits computed from PEST with $q_0 = 1$

Theoretical beta limit model $f(\ell_i, F_p)$ fits data well

- Inclusion of F_p in scaling suggests a non-linear dependence on ℓ_i

Final TFTR Experiments Integrated 3 Improvements

- Reduced limiter power load with Kr radiative mantle:
 - Rapid edge density influx (bloom) suppressed
 - Up to 90% radiated power with no reduction in η_E
- Improved recycling control with Li deposition:
 - Maximum η_E attained through edge recycling control
 - Li aerosol (DOLLOP) system to provide continuous Li injection
- Increased stability limit with high ℓ_i operation:
 - Operation at high I_p 2.3MA, B_T 5.6 T ($q^* = 3.5$)
 - Yielded high η and fusion power (P_f 8.7 MW)
